NN parameter estimation for regression

Model:

$$\mathbf{Y} = \hat{\mathbf{Y}} + \boldsymbol{\epsilon} = f(\mathbf{X}; \boldsymbol{\theta}) + \boldsymbol{\epsilon}$$

where

 $f(\mathbf{X}; \boldsymbol{\theta})$ expresses our neural network

 $\epsilon \sim N(\mathbf{Y} - f(\mathbf{X}; \boldsymbol{\theta}), \boldsymbol{\Sigma})$

=
$$\underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \log P(\mathbf{Y} | \mathbf{X}; \boldsymbol{\theta})$$

• Optimization:
$$\hat{\boldsymbol{\theta}} = \underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \log P(\mathbf{Y} | \mathbf{X}; \boldsymbol{\theta}) = P(\mathbf{Y} | \mathbf{X}; \boldsymbol{\theta})$$

$$:= P(\mathbf{Y} | \mathbf{X}; \boldsymbol{\theta})$$

=
$$\underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \log \left(\sqrt{\frac{1}{(2\pi)^N \det \boldsymbol{\Sigma}}} \exp \left[-\frac{1}{2} \left(\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}) \right)^T \boldsymbol{\Sigma}^{-1} \left(\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}) \right) \right] \right)$$

=
$$\underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \frac{1}{2} \log((2\pi)^N \det \boldsymbol{\Sigma}) - \frac{1}{2} (\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}))^T \boldsymbol{\Sigma}^{-1} (\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}))$$

= $\underset{\boldsymbol{\theta}}{\operatorname{argmin}} - (\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}))^T (\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta}))$
 $\boldsymbol{\Sigma}$ is diagonal of the sum of the

= argmin
$$-\left(\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta})\right)^T \left(\mathbf{X} - f(\mathbf{X}; \boldsymbol{\theta})\right)$$

$$= \underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \sum_{i=1}^{M} (\mathbf{y}^{(i)} - f(\mathbf{x}^{(i)}; \boldsymbol{\theta}))^{T} (\mathbf{y}^{(i)} - f(\mathbf{x}^{(i)}; \boldsymbol{\theta}))$$

$$\rightarrow \Sigma$$
 is diagonal, strictly positive, independent of x ; it doesn't affect $\hat{\theta}$

=
$$\underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \sum_{i=1}^{M} \sum_{j=1}^{N} \left(\mathbf{y}_{j}^{(i)} - f(\mathbf{x}^{(i)}; \boldsymbol{\theta})_{j} \right)^{2} \leftarrow \text{least squares}$$

NN parameter estimation for classification

Model:

$$P(\mathbf{y} | \mathbf{x}; \boldsymbol{\theta})$$
 where $\mathbf{x}, \mathbf{y} \sim P_D$, $\mathbf{y} \in \{0, 1\}^K$

• Optimization:
$$\hat{\boldsymbol{\theta}} = \underset{\boldsymbol{\theta}}{\operatorname{argmin}} \sum_{i=1}^{M} -\mathbf{y}_{i} \log P(\mathbf{y}_{i} | \mathbf{x}_{i}; \boldsymbol{\theta})$$
 one hot encoding
$$= \underset{\boldsymbol{\theta}}{\operatorname{argmin}} - \mathbb{E}_{\mathbf{x}, \mathbf{y} \sim P_{D}} \left[\log P(\mathbf{y} | \mathbf{x}; \boldsymbol{\theta}) \right]$$

$$= \underset{\boldsymbol{\theta}}{\operatorname{argmin}} \mathbb{E}_{\mathbf{x}, \mathbf{y} \sim P_{D}} \left[\log \frac{1}{P(\mathbf{y} | \mathbf{x}; \boldsymbol{\theta})} \right]$$

Cross entropy between data distribution and the model output distribution, $H(P_D(\mathbf{y}|\mathbf{x}), P(\mathbf{y}|\mathbf{x}; \boldsymbol{\theta}))$. Note, this holds for arbitrary PMFs (softmax, Bernoulli, etc...). Because the labels, y, are one hot, they have zero entropy, and thus in this setting minimizing the cross entropy is equivalent to minimizing the KL divergence, $D_{KL}(P_D(\mathbf{y}|\mathbf{x}), P(\mathbf{y}|\mathbf{x}; \boldsymbol{\theta}))$.
